

The Garry oak tree is an endangered oak tree that is only found in British Columbia and the Western United States. The Garry oak's population has decreased over the years to 15% of its original population. This is partly because only 1 in 5 planted Gary oak trees actually grow.

Their populations are further decreased by invasive species pushing out and killing the trees environments, poisoning them and trampling newly grown sprouts.

All of these factors have reduced the Garry oak ecosystem to 5% of its original state.
